## BACKGROUND OF THE INVENTION OF THE SAME STATE

### 1. Field of the Invention The second of the Invention of

The present invention relates to a positive electrode active material for allithium battery, a method for property ducing the same, and a battery containing the same in the positive electrode thereof. The property is a second and the positive electrode thereof.

### 2. Description of the Related Art (1991) 1990 of the first of the or

With the recent development of portable electronic equipment, batteries of higher performance have been in demanded. Lithium ion batteries using a carbon material in the negative electrode and lithium cobaltate (LiCoO<sub>2</sub>), which is a composite oxide having a layer structure, in the positive electrode have been put to practical in a nonaqueous battery having a high working voltage and a high energy density. Lithium nickelate (Licontaining nickel oxide; LiNiO<sub>2</sub>) is also a compound having the same layered crystal structure as the lithium cobaltate in which lithium ions are intercalated between layers of NiO<sub>6</sub> octahedral sharing edges:

Lithium nickelate is generally prepared by mixing a nickel source selected from Ni(NO<sub>3</sub>)<sub>2</sub>, Ni(OH)<sub>2</sub>, NiCO<sub>3</sub>, CC NiO, NiOOH, etc. and a lithium source selected from Si LiOH, LiNO<sub>3</sub>, Li<sub>2</sub>CO<sub>3</sub>, Li<sub>2</sub>O<sub>2</sub>, etc., and subjecting the mixture to a heat treatment at about 600 to 900°C in an 30 oxygen stream.

Since cobalt or nickel used in these active materials is expensive for scarcity, less expensive active materials for a positive electrode has been sought. For example, Li-containing manganese composite oxide (LiMn<sub>2</sub>O<sub>4</sub>) 10.35 having a spiriel structure has been proposed; but its the old oretical capacity of 148 mAh/g is low, and the reduction in capacity increases with charge and discharge cycles.

ElivinO2 has been proposed as a promising active in material for batteries with higher performance. Among 40 various phases exhibited by LIMinO25 two phases; n whose crystal structure have been well characterized, are a high temperature orthorhombic phase (Pmnm) and a low temperature tetragonal phase (141/amd). Both structures involve cubic close packing but they differ in the arrangement of the ordering of the lithium and manganese cations. The tetragonal form Li2Mn2O4 is prepared by electrochemically or chemically intercalating: lithium binto the spinel LiMn2O4[Mat. Resco Bull; 18(1983)461 & 18(1983)1375; J. Electrochem Soc. 9-50 138(1991)2864 & 139(1992)937]. The orthorhombic phase his been prepared mainly by the solid state reaction at high temperature using different precursors days Phys. Chem. Solid. 3(1957)20 & 318; J. Phys. Radium 20(1959)155; J. Anorg. Allg. Chem. 417(1975)1; Mater. Res. Bull. 28(1993)1249): However, orthorhombic LiMnO2 was reported to be prepared at low temperature using the solid state reaction by heating a mixture of  $\gamma$ -MnOOH and LiOH at 300 to 450°C [Chem: Express,

7(1992)193]. An other process for preparing the orthorhombic LiMnO<sub>2</sub> at a temperature less than 100°C by ion: exchange was reported. [J. Electrochem, Soc. 140(1993)3396; Unexamined Japanese Patent Publication (kokai): No: 6-349494]. In this case, the exchange was carried out by refluxing γ-MnOOH, under boiling condition in:LiOH-solution. So far, LiMnO<sub>2</sub> isostractural with layered LiNiO<sub>2</sub> or LiCoO<sub>2</sub> has not yet been synthesized.

Referring to LiMnO<sub>2</sub> having a layer structure, J. Solid State Chem. 104(1993)464 and U.S. Patent 5,153,081 report that LiMnO<sub>2</sub> having a monoclinic layer structure can be obtained by acid leading of Li<sub>2</sub>O out of Li<sub>2</sub>MnO<sub>3</sub>. In the first step, Li<sub>2</sub>MnO<sub>3</sub> was orepared by reacting electrolytic manganese dioxide (EMD) with a stoichiometric quantity of Li<sub>2</sub>O<sub>3</sub>. The obtained material was then delithiated using H<sub>2</sub>SO<sub>4</sub> at room temperature for 64 hours.

The thus obtained substance exhibits a discharge voltage of 3 V vs. Li/Li<sup>+</sup>. Although the reaction product exhibits a new X-ray diffraction peak at 20=19.5°, most of the other peaks correspond to the starting material which is Li<sub>2</sub>MnO<sub>3</sub> (U.S. Patent 5,153,081). Ignoring the fact that most of the peaks are assigned to the starting Li<sub>2</sub>MnO<sub>3</sub>, the inventors of U.S. Patent 5,153,081 identify the product to be a substance having a layer structure based on the peak at 20=19.5°, but the identification seems to be decisively unreasonable. In this case, the product should rather be regarded as a lithium manganese oxide having a spinel structure as a basic skeleton, such as Li<sub>2</sub>Mn<sub>4</sub>O<sub>9</sub> or Li<sub>4</sub>Mn<sub>5</sub>O<sub>12</sub>.

Further, J. Solid State Chem., 104(1993)464 reports a substance having a layer structure whose X-ray diffraction pattern is different from those of LiNiO<sub>2</sub> or LiCoO<sub>2</sub>. While not entering into details about structural refinement of the substance, the report based their layered structure on the assumption that removal of Li<sub>2</sub>O from Li<sub>2</sub>MnO<sub>3</sub> causes a shearing of the closed-packed oxygen planes to yield an oxygen array in the obtained material comprised of alternate layers of trigonal prisms where lithium is located and sheets of edge-shared octahedra where manganese is located. In this case, the manganese ions remain in alternate layers and do not migrate to the lithium layers during the leaching process, and the lithium layer is arranged in a zig-zag fashion with lithium ions in a trigonal prismatic coordination

Unexamined Japanese Patent Publication (kokai) No. 7-223819 reports that  $LiMnO_2$  having a layer structure with a lattice constant of a=3.321 Å and c=4.730 Å is obtained by electrolysis method. This material is not isostructural with  $LiNiO_2$ . Thus, no  $LiMnO_2$  having a layer structure similar to that of  $LiNiO_2$  or  $LiCoO_2$ , has been synthesized yet.

As stated above, although 4.0 V type LiMn<sub>2</sub>O<sub>4</sub> having a spinel structure has been proposed as an inexpensive Li-containing manganese composite oxide, the theoretical capacity is inferior to oxide compounds having a hexagonal layer structure, such as LiNiO<sub>2</sub> (theo-

3285

. .

7 . . .

10

retical capacity: 275 mAh/g) and LiCoO<sub>2</sub> (theoretical 3) capacity: 274 mAh/g). In addition, the charge and disc incharge cycle characteristics are better in layered oxide materials. Therefore, development of an inexpensive active material having a layer structure similar to that of 150 LiNiO<sub>2</sub> or LiCoO<sub>2</sub> and establishment of synthesis there fore have been keenly demanded, but a useful method of synthesis has not yet been established.

#### SUMMARY OF THE INVENTION

It is an object of the present invention to prepare lithium manganate with a structure different from the spinel structure of known LiMn<sub>2</sub>O<sub>4</sub> but is analogous to the hexagonal layer structure of lithium cobattate or lithe sets ium nickelate, having a space group of R3m, and is therefore expected to exhibit increased activity as a positive electrode active material for lithium batteries:

The present invention provides a positive electrode active material for lithium batteries which comprises lith 220 ium manganate having a hexagonal layer structure with the space group of R3m and exhibits continuous discharge voltage characteristics between 4.5 V and 2 V vs. Li/Lith. The active material according to the present invention as a theoretical capacity of 286 mAh/g.

The present invention also provides a method: for entire producing such a positive electrode active material and asd a battery containing the positive electrode active materials rial.

The positive electrode active material according to \$30 the present invention undergoes homogeneous reaction to exhibit continuous discharge voltage characteristics between 4.5 V and 2.0 V vs. Li/Li a The discharge characteristics are stable upon cycling, providing along to battery life. The active material of the invention is inexable pensive and economical.

### BRIEF DESCRIPTION OF THE DRAWINGS of LAW (4.5 months) and the control of the cont

Fig. 1A shows an X-ray diffraction patterns of an 40 present invention. The shows an X-ray diffraction pattern of the show present invention. The shows an X-ray diffraction pattern of LiNiO<sub>2</sub> having a layer structure; the shows an X-ray diffraction pattern of LiNiO<sub>2</sub> having a layer structure; the shows an X-ray diffraction patterns of 45 LiMnO<sub>2</sub> with orthorhombic structure obtained by a structure of the layer-structure of LiMnO<sub>2</sub> shows an illustration of the layer-structure of

LiMnO<sub>2</sub> according to the present invention; and Market Fig. 3 shows typical discharge characteristics of 1950 LiMnO<sub>2</sub> according to the present invention, the according to the present invention, the according to the present invention.

#### DETAILED DESCRIPTION OF THE INVENTION AND BUSINESS

The lithium manganate according to the invention is 55: not the known LiMnO<sub>2</sub> obtained by the reaction. between  $\gamma$ -MnOOH and LiOH in a solid phase calcination process but LiMnO<sub>2</sub> which is obtained by a hydrothermal reaction of  $\gamma$ -MnO<sub>2</sub> in an LiOH solution and has

a layer structure similar to the structure of LiNiO<sub>2</sub> or LiCoO<sub>2</sub>. The lithium manganate of the present invention can be applied as a positive electrode active material in an nonaqueous solution to provide inexpensive and high-performance batteries.

The active material according to the present invention has a layer structure similar to the structure of LiNiO<sub>2</sub> or LiCoO<sub>2</sub>et.e. a structure similar to α-NaFeO<sub>2</sub>.

The tayered structure of the active material can be described from a packing MnO<sub>2</sub> slabs built up of edge-sharing MnO<sub>6</sub> octahedra in between which lithium ions are located in the octahedral oxygen environment. This structure comprises a layer of manganese ions in octahedral environment, surrounded by oxygen ions arranged in acubic close packed arrangement resulting in the formation of sheets of edge-shared octahedra. It also comprises a lithium layer where lithium is having an octahedral environment and is sandwitched between two layers of octahedral MnO<sub>6</sub>:

The active material according to the present invention was found to have a layer-structure having a lattice constant of a=2.86 Å and c=14.23 Å similarly to LiNiO<sub>2</sub> or LiCoO<sub>2</sub>. The lattice constant is not a fixed one. That is, the unit lattice constant is subject to variation from 2.76 to 2.96 Å as for a and from 14.13 to 14.33 Å as for a according to the conditions of preparation or by addition of dopant such as nickel, cobalt zinc, etc. The active material, exhibits continuous discharge characteristics between 4.5 V and 2 V vs. Li/Li<sup>+</sup>.

The active material of the invention is preferably produced by dissolving or suspending a starting manganese salt in lithium solution and causing the solution to react in an autoclave under high pressure and low pH solution. Suitable raw manganese materials are inorganic salts such as MnQ<sub>2</sub>, Mn<sub>2</sub>Q<sub>3</sub>, MnOQH, and MnCQ<sub>3</sub>, and organic salts such as manganese accetate, manganese butyrate, manganese oxalate, and manganese citrate. Suitable raw, lithium materials are LiQH. LiNO<sub>3</sub>: Li<sub>2</sub>CO<sub>3</sub>: Li<sub>2</sub>O<sub>3</sub> lithium accetate, lithium butyrate, in the reaction are purified water, and organic solvents in the reaction are purified water, and organic solvents in the reaction is preferably carried out at a high temperature of from 100 to 300°C.

LiMnO2 having a layer structure can be synthesized by a hydrothermal process. The high-pressure and low-temperature, hydrothermal process, according to the present invention is also applicable to synthesis of other substances. Having a tayen structure, represented hydrogeneral formula AMeO2 (A:1. Naco: KraMe2MP; Nic Son) a Fe, Chor Victio and ASSI (1991) 86

#### EXAMPLES and in large price acceptained debt as multiple system. Proc 3, 2007-291(8), block press?.

Joe present invention will be described in greater detail with reference to examples, but it should be understood that the present invention is not constructed as being limited thereto.

668-mg of LiOH was dissolved in 120 ml of water at

chaso his been properly trainly by the colid state read

一、证明经过数据自然标准

50°C, and thereafter, 50 mg of  $\gamma$ -MnO $_2$  was immersed therein for 30 minutes. The pH of the solution was adjusted to 1 to 2 and the mixture was heated in an polytetrafluoroethylene-covered stainless steel autoclave at 170°C and 300 atm for 5 days to obtain lithium manganate according to the present invention.

The X-ray diffraction pattern (CuK $\alpha$ ) of the resulting active material is shown in Fig. 1A. For comparison, the diffraction pattern of LiNiO $_2$  having a layer structure is shown in Fig. 1B, and that of orthorhombic LiMnO $_2$  obtained by a conventional solid phase reaction (calcination of a mixture of  $\gamma$ -MnO $_2$  and LiOH at 700°C) is shown in Fig. 1C.

It can be seen that the diffraction pattern of the active material of the present invention is not similar to that of known orthorhombic LiMnO $_2$  but to that of LiNiO $_2$  having a layer structure. It was found that the indices of a plane of the diffraction peaks can be assigned to the layer structure of hexagonal system having a space group of R3m. The structural description of the active material of the invention is shown in Fig. 2.

The active material of the present invention has a packing structure of two  $MnO_2$  layers composed of octahedral of  $MnO_6$  sharing edges, in which a lithium ion is surrounded by oxygen ions having an octahedral coordination. In this structure, manganese ions are arranged in layers and surrounded by an octahedron of oxygen ions which are arranged in cubic closest packing to form an octahedral layer sharing edges. The lithium ion of the lithium layer is sandwitched in between two layers of octahedral of  $MnO_6$ .

It was found that the structure of the active material of the present invention is similar to the layer structure of LiNiO $_2$  or LiCoO $_2$ , typically having a unit lattice constant of a=2.86 Å and c=14.23 Å. The unit volume was 101.23 Å $^3$ , approximately the same as 101.3 Å $^3$  of LiNiO $_2$ . This means that the LiMnO $_2$  having a layer structure and LiNiO $_2$  are apt to form a solid solution. In fact, addition of nickel to LiMnO $_2$  results in stabilization of crystal properties, and the resulting solid solution was less susceptible to deterioration by charge and discharge cycles.

On the other hand, because of structural difference between orthorhombic LiMnO $_2$  and LiNiO $_2$ , orthorhombic LiMnO $_2$  forms a solid solution LiMn $_x$ Ni $_{1-x}$ O $_2$  (0 $\leq$ x $\leq$ 0.5), but the solid solution has poor charge and discharge characteristics as reported in Solid State lonics, 57(1992)311. It was confirmed that addition of cobalt to the active material of the invention produces the same effect. It is understood that the LiMnO $_2$  having a layer structure according to the invention is different from LiMnO $_2$  of orthorhombic structure the diffraction pattern of which is shown in Fig. 1C.

The active material obtained in this Example had a layer structure of perfect hexagonal system in which no substitution between manganese ions and lithium ions was observed. While structures in which lithium and manganese are substituted with each other were obtained in some cases depending on the temperature

and pressure conditions of the hydrothermal reaction, the active material principally had a layer structure.

A battery was prepared using thus obtained active material as a positive electrode active material and metallic lithium as a negative electrode. When the battery was charged to 4.2 V at a current of 0.2 C and then discharged to 2 V at the same current, satisfactory electrochemical activity was exhibited. The typical discharge characteristics are shown in Fig. 3. It is seen that stable discharge characteristics can be secured through the charge and discharge cycles. It is also seen that continuous discharge characteristics are exhibited between 4.5 V and 2 V vs. Li/Li+, which has not been reported to date. The LiMnO2 having a layer structure has now been proved to be an unreported inexpensive active material. The LiMnO2 has a theoretical capacity density of 286 mAh/g. Further optimization of electrode designing will produce higher performance.

While the present invention has been described in detail and with reference to specific examples thereof, it will be apparent to one skilled in the art that various changes and modifications can be made therein without departing from the spirit and scope thereof.

#### Claims

30

40

45

50

 A positive electrode active material for lithium batteries comprising lithium manganate having a hexagonal structure and a space group of R3m, and exhibiting continuous discharge voltage characteristics between 4.5 V and 2 V vs. Li/Li+.

growing and a

- 2. A positive electrode active material according to claim 1, wherein said lithium manganate has a unit lattice constant of a=2.76 to 2.96 Å and c=14.13 to 14.33 Å.
  - A positive electrode active material according to claim 1, further comprising at least one of nickel, cobalt, iron, chromium, zinc and vanadium.
  - 4. A battery comprising a positive electrode active material for lithium batteries comprising lithium manganate having a hexagonal structure and a space group of R3m, and exhibiting continuous discharge voltage characteristics between 4.5 V and 2 V vs. Li/Li<sup>+</sup>; and a negative electrode.
  - A battery according to claim 4, wherein said negative electrode comprises metallic lithium, carbon and metal alloys.
- 6. A battery according to claim 4, wherein said lithium manganate has a unit lattice constant of a=2.76 to 2.96 Å and c=14.13 to 14.33 Å.
  - A battery according to claim 4, wherein said positive electrode active material further comprises at least one of nickel, cobalt, zinc, iron, chromium and
